VERIFIED RECOVERY AFTER A SUPPLIER DELAY

Supply Dispatcher

01 Deterministic supplier comparison

02 Buyer approval before the order changes

03 A saved result with independent verification

A delayed supplier puts the order at risk

01 A buyer must compare price, quantity, product and delivery at once.

02 The cheapest offer can fail a mandatory requirement.

03 An explanation alone does not recover the order.

A consistent choice with a checked outcome

01 Each recommendation satisfies the declared order requirements.

02 Identical offers produce the same calculated winner.

03 Every approved action receives a durable record and independent readback.

Calculation chooses. Inference explains.

01 A fixed solver compares the current offers in an isolated container.

02 An independent implementation checks the optimum.

03 Vultr inference explains the checked choice. The buyer approves it.

One disruption, one reviewable workflow

01 Enter the delayed order and supplier alternatives.

02 Review the plan, recommendation and three analytics views.

03 Approve the replacement and inspect the verified saved result.

The selection rule is explicit

01 Product matches. Quantity covers the order. Cost and ETA fit the limits.

02 Minimize cost, then ETA, then supplier ID for an exact tie.

03 Eligibility checks keep the recommendation aligned with the order.

Every task has a bounded lifetime

01 Disposable Docker execution with no network or application secrets.

02 128 MiB RAM, 0.50 CPU, 64 processes, CPU and wall-clock limits.

03 The infinite-loop demo confirms termination, cleanup and recovery.

Running on Vultr

01 Vultr VM: Python backend, SQLite ledger and Docker task runner.

02 Vultr Serverless Inference: qwen3.8-flash-next explains the checked choice.

03 Caddy serves public HTTPS. The browser workflow used real inference.

Approval leads to a checked record

01 The host checks the sandbox optimum and mandatory constraints.

02 Approval commits supplier, cost and ETA to the order ledger.

03 A fresh connection reads back the result. Evidence records the outcome.

Evidence comes from executed checks

01 299 generated fresh-state workflow cases use an independent oracle.

02 Separate HTTP, regression and real Docker tests check boundaries.

03 Cloud checks separately verified HTTPS, inference and Docker recovery.

The buyer can explain and verify the choice

01 The cloud sample selects SYNTH-A at 1,200 within a 1,500 budget.

02 The cheaper offer arrives late. The faster feasible alternative costs 150 more.

03 The buyer can compare the alternatives and confirm the verified saved result.

Public demo and recorded evidence

01 Public source: github.com/CAPEXNULL/Vultr-Dispatcher

02 Demo: supply-dispatcher.80.240.28.98.sslip.io

03 Approved orders survived service restart and VM reboot. Cloud workflow and containment recorded.
